

开环Nyquist曲线绘制

通过判断 Q_{GH} 情况判断 Q_{GH} 稳定性

稳定性

前提: Q 上无 GH 零极点, Q 内极点 p_i 的阶数和

通过判断 Q_{GH} 情况判断 Q_{GH} 稳定性

稳定性

前提: Q 上无 GH 零极点, Q 内极点 p_i 的阶数和

通过判断 Q_{GH} 情况判断 Q_{GH} 稳定性

稳定性

前提: Q 上无 GH 零极点, Q 内极点 p_i 的阶数和

补圆:

(1) $\omega \rightarrow 0^+$ (2) 顺时针 (3) $\frac{m}{2} \rightarrow -\frac{m}{2}$

$G(s)H(s)$ 开环增益增大 α 倍, $-1 \rightarrow -\frac{1}{\alpha}$

纯滞后降低系统稳定性

设 $G(s)H(s)$ 因果且最小相位/最小相位+纯滞后

对于开环非最小相位不能用上述判据,应用Nyquist图等其他方法

工程上: $45^\circ \leq \gamma \leq 60^\circ$, $20 \lg h \geq 6 \text{ dB}$

ω_c 附近相当斜率 20 dB/dec , 则 $\angle G(j\omega_c) \approx 90^\circ$

ω_c 斜率为 -20 dB/dec

不陡于 $-40 \sim -20 \text{ dB/dec}$ 不陡于 -80

频域指标 $\gamma = -\frac{1}{20} \lg |G(j\omega_c)|$

$\gamma \leq 0$ 时可近似 $\gamma = 0.01 \gamma$

$\Rightarrow (\frac{\omega_c}{\omega_n})^4 + 4\zeta^2 (\frac{\omega_c}{\omega_n})^2 - 1 = 0$ ζ -定时:

$(1 - \frac{\omega_c}{\omega_n})^2 + 4\zeta^2 (\frac{\omega_c}{\omega_n})^2 = 0$

$\omega_c \uparrow, \omega_n \uparrow$, 响应更快 ($T_r, T_s, T_p \downarrow$)

$\omega_c \uparrow, \omega_n \uparrow$, 响应更快 ($T_r, T_s, T_p \downarrow$)

闭环谐振峰值: $M_r = \frac{1}{2\zeta\sqrt{1-\zeta^2}} \geq 1$

闭环谐振频率: $\omega_r = \omega_n \sqrt{1-2\zeta^2}$

闭环带宽频率: $\omega_b = \omega_n \sqrt{1-2\zeta^2 + \sqrt{1-4\zeta^2 + 4\zeta^4}}$

开环截止频率: $\omega_c = \omega_n \sqrt{1+4\zeta^2-2\zeta^4}$

相位裕度: $\gamma = \arctan(\frac{2\zeta}{\sqrt{1+4\zeta^2-2\zeta^4}})$

调节时间 $T_s = \frac{3.5}{\zeta\omega_n}$ $\omega_n T_s = \frac{7}{2\zeta}$

超调量 $\sigma\% = e^{-\frac{\gamma}{180} \sqrt{1-\zeta^2}} \times 100\%$

$(M_r = 1.2 \sim 1.5, \sigma = 20\% \sim 30\%; M_r > 2, \sigma > 40\%)$

稳: $\gamma \geq 45^\circ$ $20 \lg h \geq 6 \text{ dB}$

快: $\gamma \geq 60^\circ$ (防止过大) ω_c 尽量大

准: 起始 $-20 \sim -40 \text{ dB/dec}$ (I型/I2型)

低频有较高幅值 ($k \uparrow$, 稳态误差)

抗干扰: 高频斜率尽量大

低频: 稳态 中频: 稳定性与动态 高频: 抗干扰

串联校正: 低能量 $\rightarrow$ 高能量, 必须能量补偿 (有源、放大)

超前 $G(s) = \frac{1+\alpha Ts}{1+Ts}$ $\alpha > 1$ (工业 $\alpha = 10$)

$\varphi_m = \arcsin \frac{\alpha-1}{\alpha+1}$

$\varphi_m = \gamma - \gamma_0 + \varepsilon$ 增量 $15^\circ \sim 12^\circ$

要求 $\omega_m = \omega_c = \frac{1}{T}$

思路: $\varphi_m \rightarrow \alpha \rightarrow \omega_c \rightarrow T = \frac{1}{\omega_m}$

滞后: $G(s) = \frac{1+Ts}{1+\beta Ts}$ $\beta > 1$

$\varphi_m = -\arcsin \frac{\beta-1}{\beta+1}$ (降低 ω_c)

要求 $\gamma \geq 40^\circ$, 取 52°

$\varphi(0.5) = -128^\circ \therefore \omega_c = 0.5$

期望主导闭环极点在根轨迹左方 $\Rightarrow$ 提前使根轨迹向左倾斜, 振荡衰减收敛更快, 改善稳定性与动态性能

滞后使根轨迹向右倾斜, 因此不应减小根轨迹形状, 只增大开环增益 K , 减小稳态误差

K_p 放大 β 倍, 偶极子 $\frac{s-p}{s+p} = \frac{s+0.05\beta}{s+0.05} = \beta \frac{s+0.05\beta}{s+0.05}$

直接蒸汽加热模型

系统方程: $\frac{d^2 y}{dt^2} + 2\zeta\omega_n \frac{dy}{dt} + \omega_n^2 y = \omega_n^2 u$

系统方程: $\frac{d^2 y}{dt^2} + 2\zeta\omega_n \frac{dy}{dt} + \omega_n^2 y = \omega_n^2 u$

系统方程: $\frac{d^2 y}{dt^2} + 2\zeta\omega_n \frac{dy}{dt} + \omega_n^2 y = \omega_n^2 u$

例: $\ddot{y} + 28\dot{y} + 196y = 360u + 440u$

$G(s) = \frac{360s + 440}{s^2 + 28s + 196}$

设 $U(s) = (360s + 440) X(s)$

$Y(s) = (360s + 440) X(s)$

$X_1 = X, X_2 = \dot{X}, X_3 = \ddot{X}$

$\dot{X} = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -196 & -28 & 0 \end{bmatrix} X + \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} u$

常见 Laplace 变换及性质

$u(t) \leftrightarrow \frac{1}{s}$ $\sin \omega t \leftrightarrow \frac{\omega}{s^2 + \omega^2}$

$t u(t) \leftrightarrow \frac{1}{s^2}$ $\cos \omega t \leftrightarrow \frac{s}{s^2 + \omega^2}$

$e^{-at} u(t) \leftrightarrow \frac{1}{s+a}$ $e^{-at} x(t) \leftrightarrow X(s+a)$

单位抛物线 $\frac{1}{2} t^2 u(t), k=1$

稳定性判据 (LTI)

$\lim_{t \rightarrow \infty} y_c(t) = 0$

极点均在左半平面

Routh 判据

Bode图 相位裕度 $\gamma > 0$, 幅值裕度 $h > 1$

Nyquist 判据

ω_c 附近 -20 dB/dec

含纯滞后的根轨迹 $G(s)H(s)e^{-sT}$

不含纯滞后的系统有两类极点分支, 且所有 $K > 0$ 系统是稳定的, 含纯滞后的系统有无穷多个极点分支, 且根轨迹趋近于实轴, 其分支称为辅助根轨迹

系统稳定的充分必要条件是: 系统特征方程的所有根都具有负实部
